# **Predicting NBA Draftkings Scores**

**Supervised Learning Capstone** 

BY: Elijah Woolford

## Research Question:

• Can we model and accurately predict player's draftkings points from 2017-18 NBA basketball data?

- The basketball data I needed was not readily accessible from data sites such as kaggle and data.gov
- I had to scrape the data from basketball-reference.com
- Using the libraries BeautifulSoup and urlib.request, I was able to open the url https://www.basketball-reference.com and parse through the html code to get the necessary tables.

- This link contained the table I needed with all the players and links to their stats for the 2017-2018 season.
- Again using beautiful soup I was able to find the table and get the extension for each link for each player.

- With all the links to each of the player's datatables, I removed any duplicate links and once again used beautiful soup to parse through each link and find the table with the data.
- With each table I iterated through each row and column and saved the data in a list as comma separated strings.
- Finally I wrote each player line to a csv file to be imported as a dataframe.

- After scraping the data and doing some cleaning, it was time to choose and create features.
- First I wanted to see what columns in the data table are correlated with DK points.

#### Draftkings NBA Scoring System:

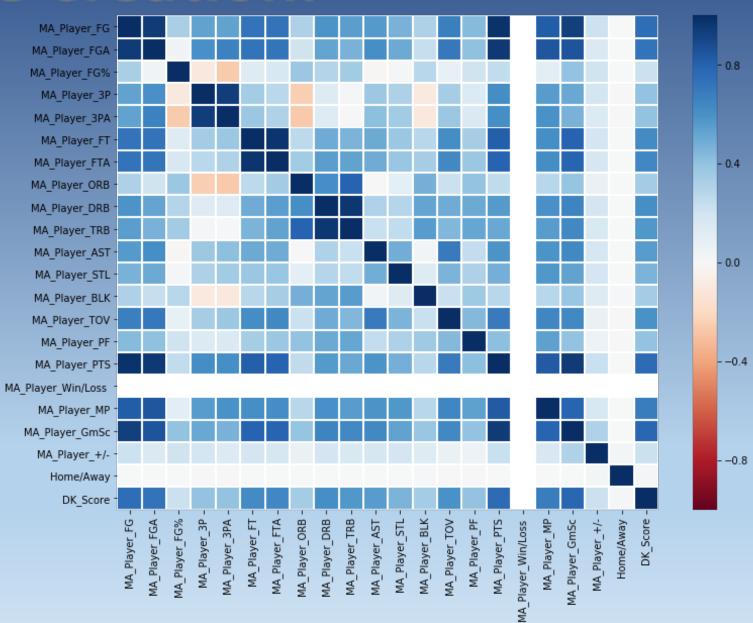

- Point +1 Pt
- Made 3pt Shot +0.5 Pts
- Rebound +1.25 Pts
- Assist +1.5 Pts
- Steal +2 Pts
- Block +2 Pts
- Turnover -0.5 pts

- Double-Double {Max 1 Per Player: Points, Rebounds, Assists, Blocks, Steals} +1.5 Pts
- Triple-Double {Max 1 Per Player: Points, Rebounds, Assists, Blocks, Steals} +3 Pts

- Looking at the features we see that most of the columns have a positive correlation with DK scores.
- The ones that stand out the most are FG, FGA, MP, PTS, and GmSc
- But we run into issues because we won't have any of the columns before the game is played in order to predict the DK score of the player

- So to solve this I decided to use the moving averages on the previous games to try to predict what the actual game columns would be.
- A lot of players' draftkings points are based on streaks. So using a moving average would help catch those streaks (indications of higher averages) and help accurately predict these scores.

# Modeling:

- I decided to try out two different regression models to see if performance differs between the models:
- Linear Regression
- Ridge Regression

## **Modeling: Linear Regression**

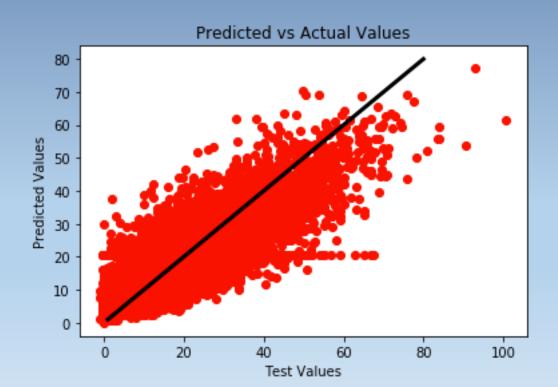

• Using Linear regression with the created features we see that there is some signal for the predicted test values compared to the actual test values but could still use some improving.

#### Cross Val Scores:

0.59734155, 0.60200847,

0.60762156, 0.60145765,

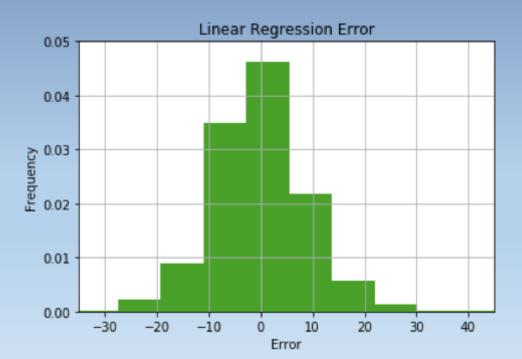

0.61501582, 0.59486526

## **Modeling: Linear Regression**

• Here are some more metrics I used to further evaluate the model:

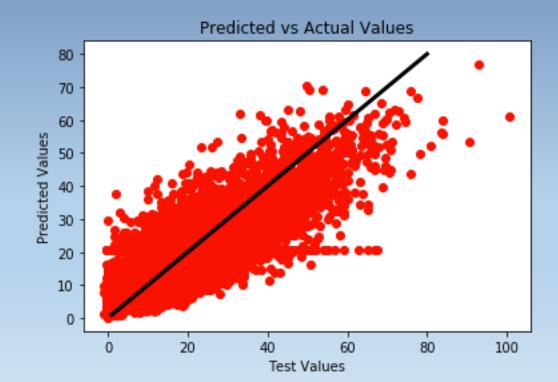

- Actual test value mean: 20.903089887640448
- Predicted test value mean: 20.975292680914517
- Mean absolute error: 6.8039056518838406

## Modeling: Ridge Regression

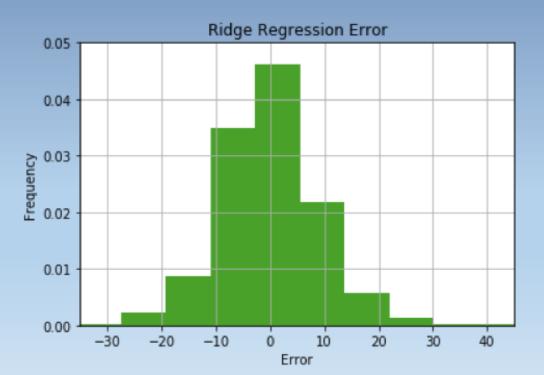

- Like Linear Regression, ridge regression shows signals but need for improvement.
- Although these features are pretty correlated, adjusting the alpha dose not significantly change much of the performance.

Cross Val Scores: 0.59734041, 0.60138892, 0.60818722, 0.60157627, 0.61567429, 0.59491193

## Modeling: Ridge Regression

- The Linear Regression model and the Ridge Regression almost had identical performances
- Actual test value mean: 20.903089887640448
- Predicted test value mean: 20.985472179811175
- Mean absolute error: 6.800937471272061

## Improvements:

- Going back to feature creation we can create more features to further highlight some of the columns that are highly correlated with DK score.
- Also, accounting for player coming off and getting injuries can help since historically a player performs a little under average when this happens.
- Scraping some player advanced stats from basketball-reference.com and calculating more moving averages should improve these models.
- Incorporating team defensive features could also improve things.

### **Further Research:**

- This project can go a step further with incorporating draftkings' salaries and lineup construction.
- Draftkings assigns a particular price tag to each player and gives a \$50,000 salary cap that a person can't exceed.
- We have to pick 8 players while staying under that salary cap.

### **Further Research:**

- I will incorporate classifier models to help classify over/under priced players based off of salary.
- Also, I would like to build a lineup generator that further classifies the players to choose the highest possible scoring lineup at the "cheapest" salary
